Situated Meaning in Multimodal Dialogue: Human-Robot and Human-Computer Interactions

James Pustejovsky* – Nikhil Krishnaswamy* **

ABSTRACT. The demand for more sophisticated natural human-computer interactions is rapidly increasing, as users become more accustomed to conversation-like interactions with their devices. Similarly, recent work in human-robot interactions (HRI) and communication has moved towards more serious dialogue modeling to facilitate deeper language understanding in context. In order to achieve these goals, human-computer/robot interactions requires robust recognition and generation of expressions through multiple modalities (language, gesture, vision, action); and the encoding of SITUATED MEANING: this entails three aspects of common ground interpretation: (a) the situated grounding of expressions in context; (b) an interpretation of the expression contextualized to the dynamics of the discourse; and (c) an appreciation of the actions and consequences associated with objects in the environment. In this paper, we describe an approach to modeling human-computer interactions based on the multimodal simulation platform VoxWorld. A multimodal simulation is an embodied 3D virtual realization of both the situational environment and the co-situated agents, as well as the most salient content denoted by communicative acts in a discourse. It is built on the modeling language VoxML, which encodes objects with rich semantic typing and action affordances, and actions themselves as multimodal programs, enabling contextually salient inferences and decisions in the environment. Since a simulation reveals the elements of the common ground in discourse between speakers, it offers a rich platform for studying the generation and interpretation of expressions, as conveyed through multiple modalities, including: language, gesture, and the visualization of objects moving and agents acting in their environment.

RÉSUMÉ. Le résumé est à écrire ici.

KEYWORDS: Multimodal dialogue, affordances, qualia structure, continuations, gesture, simulations, common ground, situated meaning, semantic grounding, referring expressions. MOTS-CLÉS: mot-clé₁, mot-clé₂, mot-clé₃.

1. Introduction

When humans communicate with each other through language, there is a shared understanding of both an utterance meaning (content) and the speaker's meaning in the specific context (intent). The ability to link these two is the act of situationally grounding meaning to the local context, typically referred to as "establishing the common ground" between interlocutors (Stalnaker, 2002; Asher, 1998). Language use may reflect only a subset of all properties of the current situation, where a full description may be impossible or at least unwieldy. Some kinds of information may in fact be more efficiently communicated using other modalities, such as gesture (e.g., deixis for pointing), demonstration or action, images, or some other visual modality. A central component to the contextualized interpretation of meaning in a discourse is the situational determination of the meanings of expressions given the common ground. It is this notion of *situated meaning* that is missing in most current human-computer and human-robot interaction models, and the focus of the present paper.

In this paper, we argue that the problem of situational awareness and the creation of *situated meaning* in discourse involves at least three components: (a) the situated *grounding* of expressions in context; (b) an interpretation of the expression contextualized to the *dynamics* of the discourse; and (c) an appreciation of the *actions and consequences* associated with objects in the environment. In Section 2, we expand on these aspects of meaning in some detail, and then in Section 3, we adopt the modeling language, VoxML, designed to encode non-linguistic, multimodal aspects of meaning associated with concepts. In section 4, we present a computational framework, Vox-World, within which these components are operationalized to facilitate multimodal communication between humans and robots or computers. Section 5 outlines a framework within which to interpret multimodal expressions, while Section 6 presents experimental evidence from single and mixed modality dialogues, illustrating the different ways in which meaning is situated in goal-directed dialogues.

2. Interactions in the Common Ground

There has been a growing interest in the Human-Robot Interaction community on how to contextually resolve ambiguities that may arise from communication in situated dialogues, from earlier discussions on how HRI dialogues should be designed (Kruijff *et al.*, 2010; Fischer, 2011; Scheutz *et al.*, 2011), how perception and grounding can be integrated into language understanding (Landragin, 2006; Muller and Prévot, 2009), to recent work on task-oriented dialogues (Tellex *et al.*, 2020). This is the problem of identifying and modifying the *common ground* between speakers (Clark and Brennan, 1991; Stalnaker, 2002; Asher, 1998; Tomasello and Carpenter, 2007). While it has long been recognized that an utterance's meaning is subject to contextualized interpretation, this is also the case with gestures in task-oriented dialogues. For example, depending on the situation, an oriented hand gesture could refer either to an action request ("move it") or a dismissive response ("forget it") (Williams *et al.*, 2019). Even a request for action can be underspecified, denoting either a continuous movement or a movement to a specific location. Similarly, depending on the situation, the definite description in the command "Open the box." may uniquely refer or not, depending on how many boxes (if any) are in the context. These and similar miscommunications or the need for clarification in dialogue have been called *situated grounding problems* (Marge and Rudnicky, 2013), and can be viewed as problematic only in a model that appeals to and encodes both a visual modality and situational information into the dialogue state. What the occurrence of these issues makes apparent is the complexity underlying the interpretation of referential expressions in actual situated dialogues. The richness provided by situationally grounding computer or robot behaviors brings to the surface interpretive questions similar to those exhibited by a human in the same scenario.

Some recent efforts have been made to provide contextual grounding to linguistic expressions. For example, work on "multimodal semantic grounding" within the natural language processing and image processing communities has resulted in a number of large corpora linking words or captions with images (cf. (Chai *et al.*, 2016)). In this paper, we argue that language understanding and linking to abstract instances of concepts in other modalities is insufficient; *situated grounding* entails knowledge of situation and contextual entities beyond that provided by a multimodal linking approach (cf. (Kennington *et al.*, 2013)).

Actual situated meaning is much more involved than aligning captions and bounding boxes in an image: e.g., (Hunter *et al.*, 2018) discuss the contribution of nonlinguistic events in situated discourse, and also whether they can be the arguments to discourse relations. Similarly, it is acknowledged that gesture is part of either the direct content of the utterance (Stojnić *et al.*, 2019) or cosuppositional content (Schlenker, 2018). Hence, we must assume that natural interactions with computers an

et al., 2019) or cosuppositional content **Figure 1.** *Mother and son interacting* (Schlenker, 2018). Hence, we must assume *in a shared task of icing cupcakes.* that natural interactions with computers and robots have to account for interpreting and generating language and gesture.

Consider the joint activity shown in Figure 1 above between a mother and her son, where they are engaged in icing cupcakes in a kitchen setting. The dialogue in Figure 2 illustrates some possible multimodal expressions used in such a context of joint activity between two agents.

SITUATED MEANING IN A JOINT ACTIVITY SON: Put it there (gesturing with co-attention)? MOTHER: Yes, go down for about two inches. MOTHER: OK, stop there. (co-attentional gaze) SON: Okay. (stops action) MOTHER: Now, start this one (pointing to another cupcake).

Figure 2. Dialogue.

Viewed as a multi-agent collaborative task interaction, there are some obvious elements constituting the common ground between the two agents in Figure 1. These include reference to: the participants (agents); shared beliefs and assumptions; shared goals and intentions; the accompanying objects in the situation; the shared perception of these objects; and the surrounding space within which the situation unfolds. Some of these elements are given below in Figure 3.

Agents	mother, son
Shared goals	baking, icing
Beliefs, desires,	Mother knows how to ice, bake, etc.
intentions	Mother is teaching son
Objects	Mother, son, cupcakes, plate, knives, pastry bag, icing, gloves
Shared perception	the objects on the table
Shared Space	kitchen

Figure 3. Elements from the common ground for Figure 1.

From this example, it is apparent that we can identify three core aspects of meaning that contribute to the common ground in a multimodal dialogue:

1) *Co-situatedness* and *co-perception* of the agents, such that they can interpret the same situation from their respective frames of reference. This might be a human and an avatar perceiving the same virtual scene from different perspectives; or a human sharing the perspective of a robot as it navigates through a disaster zone.

2) *Co-attention* of a shared situated reference, which allows more expressiveness in referring to the environment (i.e., through language, gesture, visual presentation, etc.). The human and avatar might refer to objects in multiple modalities with a common model of differences in perspective-relative references (e.g., "your left, my right"); or the human sharing the robot's perspective might be able to direct its motion using reference in natural language ("go through the second door on the left") or gesture ("go this way," with pointing).

3) *Co-intent* of a common goal, such that adversarial relationships between agents reflect a breakdown in the common ground. A human and avatar interacting around a table might seek to collaborate to build a structural pattern known to one or both of them; or the human and robot sharing perspective both have a goal to free someone trapped behind a door in a fire. The robot informs the human about the situation and the human helps the robot problem-solve in real time until the goal is achieved.

What this suggests is that any robust communication between humans and computers or robots will require at least three capabilities: (a) a robust recognition and generation within multiple modalities; (b) an understanding of contextual grounding and co-situatedness in the conversation; and (c) an appreciation of the consequences of behavior and actions taking place throughout the dialogue. To this end, in our work, we have developed a platform making use of semantically interpreted *multimodal simulations*, which provides an approach to modeling human-computer communication by both situating and contextualizing the interaction, thereby visually demonstrating what the co-agent computer or robot is hearing, seeing, thinking, and doing. This platform is based on VoxML, a modeling language for encoding traditionally nonlinguistic, multimodal, aspects of meaning associated with the objects that we encounter, manipulate, and explore in our environment. We turn to this discussion in the next section.

3. VoxML: Encoding Knowledge of Action and Behavior

Here we argue that a significant part of any model for situated communication is an encoding of the semantic type, functions, purposes, and uses introduced by the objects under discussion. I.e., a semantic model of perceived *object teleology*, as introduced by Qualia Structure, for example (Pustejovsky, 1995), as well as *object affordances* (Gibson, 1977) is needed to help ground expression meaning to speaker intent.

Objects under discussion in discourse (cf. (Ginzburg, 1996)) can be partially contextualized through their semantic type and their qualia structure: e.g., a food item has a TELIC value of *eat*, a pencil, a TELIC of *write*, a box, a CHAIR of *sit_in*, and so forth. However, while an artifact may be designed for a specific purpose, this can only be achieved under specific circumstances. To account for this context-dependence, (Pustejovsky, 2013) enriches the lexical semantics of words denoting artifacts (the TELIC role specifically) by introducing the notion of an object's *habitat*, which encodes these circumstances. For example, an object, x, within the appropriate context C, performing the action π will result in the intended or desired resulting state, \mathcal{R} , i.e., $C \rightarrow [\pi]\mathcal{R}$. That is, if the habitat C (a set of contextual factors) is satisfied, then every time the activity of π is performed, the resulting state \mathcal{R} will occur. The precondition context C is necessary to specify, since this enables the local modality to be satisfied.

The habitat for an object is situated within an *embedding space* and then contextualized within it. For example, in order to use a glass to drink from, the concavity has to be oriented upward, the interior must be accessible, and so on. Similarly, a chair must also be oriented up, the seat must be free and accessible, it must be large enough to support the user, etc. An example of what the resulting knowledge structure for the habitat of a chair is shown below, where these constraints are superscripted with '*'.

(1)
$$\lambda x \begin{bmatrix} \text{chair}(\mathbf{x}) \\ F = [phys(x), on(x, y_1)^*, in(x, y_2)^*, clear(x_1)^*, orient(x, up)^*, \\ support(x_1, y_3)^*] \\ C = [seat(x_1), back(x_2), legs(x_3)] \\ T = \lambda z \lambda e[\mathcal{C} \to [sit(e, z, x)]\mathcal{R}_{sit}(x)] \\ A = [made(e', w, x)] \end{bmatrix}$$

The notion of habitat and the attached behaviors that are associated with an object are further developed in (Pustejovsky and Krishnaswamy, 2016), where an explicit connection to Gibson's ecological psychology is made (Gibson, 1979), along with a direct encoding of the *affordance structure* for the object (Gibson, 1977). The affordance structure available to an agent, when presented with an object, is the set of actions that can be performed with it. We refer to these as GIBSONIAN affordances, and they include "grasp", "move", "hold", "turn", etc. This is to distinguish them from more goal-directed, intentionally situated activities, what we call TELIC affordances.

VoxML (Visual Object Concept Modeling Language) is a modeling language for constructing 3D visualizations of concepts denoted by natural language expressions, and is being used as the platform for creating multimodal semantic simulations in the context of human-computer and human-robot communication (Pustejovsky and Krishnaswamy, 2016; Krishnaswamy and Pustejovsky, 2016). It adopts the basic semantic typing for objects and properties from Generation Lexicon and the dynamic interpreta-

tion of event structure developed in (Pustejovsky and Moszkowicz, 2011), along with a continuation-based dynamic interpretation for both sentence and discourse composition (De Groote, 2001; Barker and Shan, 2014; Asher and Pogodalla, 2010).

VoxML forms the scaffolding we use to encode knowledge about objects, events, attributes, and functions by linking lexemes to their visual instantiations, termed the "visual object concept" or *voxeme*. In parallel to a lexicon, a collection of voxemes is termed a *voxicon*. There is no requirement on a voxicon to have a one-to-one correspondence between its voxemes and the lexemes in the associated lexicon, which often results in a many-to-many correspondence. That is, the lexeme *plate* may be visualized as a [[SQUARE PLATE]], a [[ROUND PLATE]], or other voxemes, and those voxemes in turn may be linked to other lexemes such as *dish* or *saucer*. Each voxeme is linked to either an object geometry, a program in a dynamic semantics, an attribute set, or a transformation algorithm, which are all structures easily exploitable in a rendered simulation platform.

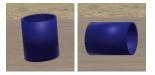

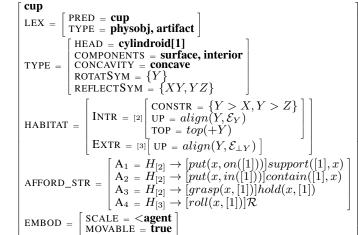

Figure 4. *Cups in different habitats.*

An OBJECT voxeme's semantic structure provides *habitats*, which are situational contexts or environments conditioning the object's *affordances*, which may be either "Gibsonian" affordances (Gibson, 1977) or "Telic" affordances (Pustejovsky, 1995; Pustejovsky, 2013). A habitat specifies how an object typically occupies a space. When we are challenged with computing the em-

bedding space for an event, the individual habitats associated with each participant in the event will both define and delineate the space required for the event to transpire. Affordances are used as attached behaviors, which the object either facilitates by its geometry (Gibsonian) or purposes for which it is intended to be used (Telic). For example, a Gibsonian affordance for [[CUP]] is "grasp," while a Telic affordance is "drink from." This allows procedural reasoning to be associated with habitats and affordances, executed in real time in the simulation, inferring the complete set of spatial relations between objects at each frame and tracking changes in the shared context between human and computer.

Indeed, object properties and the events they facilitate are a primary component of situational context. Within the environment shown in Fig. 4, we understand that both cups are able to be moved by a human: that is, they afford movement to an agent able to enact such an event. From their relative orientations (habitats), we furthermore perceive that the cup on the left is in a position to be *slid* across its supporting surface while the cup on the right can be *rolled* (in addition to being slid, cf. (2)). This voxeme for [[CUP]] gives the object appropriate lexical predicate and typing (a *cup* is a PHYSICAL OBJECT and an artifact). It denotes that the cup is roughly cylindrical and concave, has a surface and an interior, is symmetrical around the Y-axis and across associated planes (VoxML adopts 3D graphics convention where the Y-axis is vertical), and is smaller than and movable by the agent. The remainder of VoxML typing structure is devoted to habitat and affordance structures, which we discuss below.

One of the major improvements to the notion of habitat developed in VoxML over that given originally in (Pustejovsky, 2013) is how the preconditions to actions are encoded and scoped. Notice how in the example in (1), the constraint on relative size of the chair to its user (along with all constraints) is specified outside the modal context in the TELIC, while the VoxML representation using Habitats in (3) provides a reentrant binding for the situational variables.

(3) Habitat and affordance structure for *chair*: $\begin{bmatrix} chair \\ HABITAT = \begin{bmatrix} INTR = [2] \\ UP = align(Y, \mathcal{E}_Y) \\ TOP = top(+Y) \end{bmatrix} \end{bmatrix}$ AFFORD_STR = $\begin{bmatrix} A_1 = H_{[2]} \rightarrow [sit(y, on([1]))]support([1], y) \end{bmatrix}$

VoxML treats actions and events within a dynamic event semantics as programs (Pustejovsky and Moszkowicz, 2011; Mani and Pustejovsky, 2012; Pustejovsky, 2021). The advantage of adopting a dynamic interpretation of events is that one can map linguistic expressions directly into simulations through an operational semantics (Miller and Johnson-Laird, 1976). Models of processes using updating typically make reference to the notion of a state transition (Harel, 1984). Each event, such as *put* in (4), can be seen as a traced structure over a Labeled Transition System. The approach is similar in many repsects to that developed in both (Fernando, 2009; Fernando, 2013) and (Naumann, 2001).

This also allows the system to reason about objects and actions independently. When simulating the objects alone, the simulation presents how the objects change in the world. By removing the objects and presenting only the actions that the viewer would interpret as *causing* the intended object motion (i.e., an embodied agent pantomiming the object motion), the system presents a "decoupled" interpretation of the action, for example, as an animated gesture that traces the intended path of motion. By composing the two, it demonstrates a particular instantiation of the complete event.

(2) Objects encoding semantic type, habitat, and affordances:

This allows an embodied situated simulation approach to easily compose objects with actions by directly interpreting at runtime how the two interact.

(4) Events as Programs:

```
\begin{bmatrix} put \\ LEX = \begin{bmatrix} PRED = put \\ TYPE = transition_event \end{bmatrix} \\ HEAD = transition \\ ARGS = \begin{bmatrix} A_1 = x:agent \\ A_2 = y:physobj \\ A_3 = z:location \end{bmatrix} \\ BODY = \begin{bmatrix} E_1 = grasp(x, y) \\ E_2 = [while(hold(x, y), move(x, y)] \\ E_3 = [at(y, z) \rightarrow ungrasp(x, y)] \end{bmatrix} \end{bmatrix}
```

4. VoxWorld: A Platform for Multimodal Simulations

In this section, we introduce a simulation framework, VoxWorld, that situates an embodied agent in a multimodal simulation, with the capability of understanding and generating language and gesture, and the ability to synthetically perceive an interlocutor human as well as objects in its virtual surroundings, and act on them through a limited inventory of actions.

4.1. Modes of Simulation

The concept of simulation has played an important role in both AI and cognitive science for over 40 years. The two most common uses for the term *simulation* as used in computer science and AI include: (a) *computational simulation modeling*, where variables in a model are set, the model is run, and the consequences of all possible computable configurations become known; and (b) *situated embodied simulations*, where an environment allows a user to interact with objects in a "virtual or simulated world", where the agent is embodied as a dynamic point-of-view or avatar in a proxy situation. Such simulations are used for training humans in scripted scenarios, such as flight simulators, battle training, and of course, in video gaming, where the goal is to simulate an agent within a situation.

Simulation has yet another meaning, where starting with (Craik, 1943), we encounter the notion that agents carry a mental model of external reality in their heads. (Johnson-Laird, 1987) develops his own theory of a mental model, which represents a situational possibility, capturing what is common to all the different ways in which the situation may occur. This is used to drive inference and reasoning, both factual and counterfactual. Simulation Theory, as developed in philosophy of mind, has focused on the role "mind reading" plays in modeling the mental representations of other agents and the content of their communicative acts (Goldman, 2006). Simulation semantics (Feldman, 2010; Narayanan, 2010) argues that language comprehension is accomplished by means of such mind reading operations. Similarly, within psychology, there is an established body of work arguing for "mental simulations" of future or possible outcomes, as well as interpretations of perceptual input (Barsalou, 1999). These approaches we refer to as *embodied theories of mind*.

4.2. VoxWorld

VoxWorld integrates the functionality and the goals of all three approaches above. Namely, the platform situates an embodied agent in a multimodal simulation, with mind-reading interpretive capabilities, facilitated through assignment and evaluation of object and context parameters within the environment being modeled. Vox-World is based on the semantic scaffold provided by the VoxML modeling language (Pustejovsky and Krishnaswamy, 2016), which provides a dynamic, interpretable model of objects, events, and their properties. This allows us to create visualized simulations of events and scenarios that are rendered analogues to the "mental simulations" discussed above. VoxSim (Krishnaswamy and Pustejovsky, 2016) serves as the event simulator within which these simulations are created and rendered in real time, serving as the computer's method of visually presenting its interpretation of a situation or event. Because modalities are modes of presentation, a multimodal simulation entails as many presentational modes as there are modalities being modeled. The visual modality of presentation (as in embodied gaming) necessitates "situatedness" of the agent, as do the other perceptual modalities. Therefore, when we speak of *multimodal simulations*, they are inherently situated. In a human-computer interaction using such a simulation, the simulation is a demonstration of the computational agent's "mind-reading" capabilities (an agent simulation). If the two are the same (where the agent is a proxy for the player or user), then the "mind-reading" is just a demonstration of the scenario. If, on the other hand, the two are separate (agent is *not* proxy for the user), then the simulation/demonstration communicates the agent's understanding of the user and the interaction. In this case, this demonstration entails the illustration of both epistemic and perceptual content of the agent. The current architecture of the VoxWorld system is shown in Figure 5.

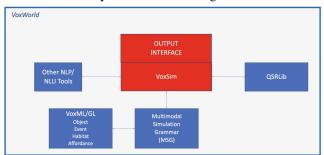

Figure 5. VoxWorld Architecture schematic

At the center is VoxSim, the software that handles visual event simulation in three dimensions, written with the Unity game engine. VoxSim connects to a number of other default VoxWorld components, including some native natural language processing capabilities, VoxML encodings/GL knowledge as interpreted through the multimodal semantics discussed in Section 5, and 3rd-party libraries, e.g., QSRLib (Gatsoulis *et al.*, 2016). Individual agent, such as the interactive avatar Diana (discussed below), are arbitary output interfaces that can also connect to 3rd-party endpoints; in the case of Diana, this is custom gesture and affect recognition (Narayana *et al.*, 2018).

Situational embodiment takes place in real time, so in the case of a situation where there may be too many variables to predict the state of the world at time t from a set of initial conditions at time 0, situational embodiment within the simulation allows the agent to reason forward about a specific subset of consequences of actions that may be taken at time t, given the agent's current conditions and surroundings. Situatedness and embodiment is required to arrive at a complete, tractable interpretation given any element of non-determinism. For example, an agent trying to navigate a maze from start to finish could easily do so with a map that provides complete, or at least sufficient, information about the scenario. If, however, the scene includes a disruptor (e.g., the floor crumbles, or doors open and shut randomly), the agent would be unable to plot a course to the goal. It would have to start moving, assess the current circumstances at every timestep, and choose the next move or next set of n moves based on them. Situated embodiment allows the agent to assess the next move based on the current set of relations between itself and the environment (e.g., ability to move forward but not leftward at the current state). This provides for reasoning that not only saves computational resources but performs more analogously to human reasoning than non-situated, non-embodied methods.

The current implementation of VoxSim provides scenes in a Blocks World domain, augmented with a set of more complicated or interesting everyday objects (e.g., cups, plates, books, etc.). There are scenes without an avatar where the user can direct the computer to manipulate objects in space or with an avatar that can act upon objects and respond to the user's input. VoxWorld contains other software, models, and interfaces, e.g., to consume input from CNN-based gesture recognizers (Narayana *et al.*, 2018), and to track and update the agent's epistemic state or knowledge about what the human interlocutor knows.

It is a straightforward process to create new scenes with 3D geometries with packaged code that handles the creates and instantiation of voxemes, handles their interactions and performs basic spatial reasoning over them. We also provide a library of basic motion predicates and methods of composing them into more complex actions using VoxML. Given the continuous tracking of object parameters such as position and orientation, facilitated by a game engine or simulation, and the knowledge of object, event, and functional semantics facilitated by a formal model, an entity's interpretation at runtime can be computed in conjunction with the other entities it is currently interacting with and their properties. One such canonical example would be placing an object [[SPOON]] in an [[IN]] relation with another object [[MUG]] (Fig. 6).

Figure 6. [[SPOON IN MUG]]

The mug has an intrinsic top, which is aligned with the upward Y-axis of the world or embedding space (denoted in VoxML as $\{align(Y, \mathcal{E}_Y), top(+Y)\}$). The mug is also a concave object, and the mug's geometry (the [[CUP]], excluding the handle) has reflectional symmetry across its inherent (object-relative) XY- and YZ-planes, and rotational symmetry around its inherent Y-axis such that when the object is situated in its inherent *top* habitat, its Y-axis is parallel to the world's. From this we can infer that the *opening* (e.g., access to the concavity) must be along the Y-axis. Encoding the object's concavity also allows fast computation for physics and collisions using bounding boxes, while still facilitating reasoning over concave objects.

An embodied simulation model such as VoxWorld is an approach that integrates all three aspects of simulation: a situated embodied environment built on a game engine platform. The computer, either as an embodied agent distinct from the viewer, or as the totality of the rendered environment itself, presents an interpretation (*mind*reading) of its internal model, down to specific parameter values, which are often assigned for the purposes of testing that model. As such, it provides a rich environment within which to experiment with task-oriented dialogues, such as those explored in Section 6, because of the requirement that the agent have a situated embodiment in which it interprets its environment and its interlocutor. This in turn requires the creation of common ground (CG) between the human and the AI that allows them to communicate. The parameters within this CG structure can be varied and set according to various experimental configurations, allowing us to both qualitatively and quantitatively measure the effect of different CG structures on the communication. For example, we can experiment with variable settings for the composition of multimodal referring descriptions as well as action or event predicates; that is, what aspects of the content of the expression are conveyed through each modality, speech or gesture? Another variation involves the degree of alignment of information in each modal channel; that is, whether a linguistic expression and gesture are synchronous or asynchronous when generated. The interaction in Figure 7 illustrates a person directing an avatar to pick up a block, using an asynchronous multimodal expression.

Figure 7. Asynchronous ensemble dialogue: Human grasping gesture precedes his linguistic utterance, "Grab it".

We assume that a simulation is a contextualized 3D virtual realization of both the situational environment and the co-situated agents, as well as the most salient content denoted by communicative acts in discourse between them. The encoding that VoxML provides for objects, with its rich semantic typing and action affordances, enables VoxWorld to describe agent actions as multimodal programs, as well as identifying and tracking the elements of the common ground that are revealed in the interaction between parties, be they humans or artificially intelligent agents.

5. Multimodal Semantics for Common Ground

The theory of common ground has a rich and diverse literature concerning what is shared or presupposed in human communication (Clark and Brennan, 1991; Stalnaker, 2002; Asher, 1998; Ginzburg and Fernández, 2010; Tomasello and Carpenter, 2007). With the presence of a common ground during shared experiences, embodied communication assumes that agents have an ability to understand one another in a shared context, through the use of co-situational and co-perceptual anchors, along with a means for identifying such anchors, such as gesture, gaze, intonation, and language.

To this end, we assume generally a model of discourse semantics as proposed in (Asher and Lascarides, 2003), as it facilitates the adoption of a continuation-based semantics for our phrase-level compositional semantics (Barker and Shan, 2014), as well for discourse, as outlined in (De Groote, 2001) and (Asher and Pogodalla, 2010). For the present discussion, however, we will not refer to SDRT representations, but focus instead on the semantics integrated multimodal expressions in the context of task oriented dialogue, as presented first in (Pustejovsky, 2018) and extended here.

We assume that the common ground structure associated with a state in a dialogue or discourse, can be modeled as a state monad (Unger, 2011; Bekki and Masuko, 2014), as illustrated in (5).

(5) State Monad: $\mathbf{M}\alpha = State \rightarrow (\alpha \times State)$

A state monad corresponds to those computations that read and modify a particular state (Wadler, 1995), in this case a state in the discourse. **M** is a type constructor that constructs a function type taking a state as input and returns a pair of a value and a new or modified state as output. This monad consists of the following state information:

- (6) a. The communicative act, C_a , performed by an agent, a: a tuple of expressions from the modalities involved. For our present discussion, we restrict this to a linguistic utterance, S (speech) and a gesture, G. There are hence three possible configurations in performing a C: $C_a = \{(G), (S), (S, G)\}$
 - b. A: The agents engaged in communication;
 - c. B: The shared belief space;
 - d. P: The objects and relations that are jointly perceived in the environment;
 - e. \mathcal{E} : The embedding space that both agents occupy in the communication.

This can be represented graphically as in (7), where an agent, a_i , makes a communicative act through either through gesture, \mathcal{G} in (7a), or linguistically, as in (7b.)¹

	A: a_1, a_2 B: Δ P: $b \in \mathcal{E} : E$	A: a_1, a_2 B: Δ P: $b \in \mathcal{E} : E$	٦
(7) a.	\mathcal{G}_{a_1}	b. $\begin{array}{c} \mathbf{A}.a_1, a_2 \mathbf{B}.\Delta \mathbf{I}.b \mathcal{C} \in D\\ \mathcal{S}_{a_1} = \text{``You}_{a_2} \text{ see it}_b \text{''} \end{array}$	
	\mathcal{G}_{a_1}		

(7a) specifies that two agents, a_1 and a_2 , co-inhabiting an embedding space, E, within which the experience is embodied, share a set of beliefs, Δ , where they can both see

¹This is similar in many respects to the representations introduced in (Cooper and Ginzburg, 2015; Ginzburg and Fernández, 2010) and (Dobnik *et al.*, 2013) for modeling action and control with robots.

the object, b. Given this representation, the gesture is now situated to refer to objects and knowledge within the CG structure. In (7b), the linguistic expression, S_{a_1} , is grounded relative to the parameters of common ground, where the indexical *you* will denote the agent, a_2 , and the pronoun *it* will denote the object, b.

For the purpose of action recognition, it has proved useful to adopt the approach taken in (Kendon, 2004) and (Lascarides and Stone, 2009), where gestures are seen as simple schemas, consisting of distinct sub-gestural phases, where **Stroke** is the content-bearing phase of the gesture.

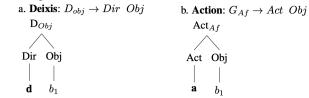

(8) $G \rightarrow (Prep) (Pre_stroke Hold)$ Stroke Retract

In the context of our multimodal dialogues and interactions with both computational agents and robots, the **Stroke** of a gesture can denote a range of primitive action types, \mathcal{ACT} , including: *grasp*, *hold*, *pick up*, *move*, *throw*, *pull*, *push*, *separate*, and *put together*. Procedurally, there are a number of ways of conveying the intent to carry out one of these actions, but they all involve two characteristics: (a) the action object is an embodied reference in the common ground; and (b) the gesture sequence must be interpreted dynamically, in order to correctly compute the end state of the event. To this end, we distinguish two kinds of gestures in our dialogues: (a) establishing a reference; and (b) depicting an action-object pair.

- (9) a. **Deixis**: $D_{obj} \rightarrow Dir \ Obj$
 - b. Action: $G_{Af} \rightarrow Act \ Obj$

The interpreted structure in (10a) indicates that the gesture D_{obj} functionally consists of a deictic orientation, Dir, with the demonstratum, **d**, and the referenced or denoting entity, Obj, denoting b_1 .

(10) Interpreted Gesture Tree:

As gesture is intended for visual interpretation, it is directly interpretable by the interlocutor in the context if and only if the value is clearly evident in the common ground, most likely through visual inspection. Directional or orientational information conveyed in a gesture identifies a distinct object or area of the embedding space, E, by directing attention to the End of the designated pointing ray (or cone) trace (Lascarides and Stone, 2009; Lücking *et al.*, 2015; Pustejovsky, 2018).

(11) $\llbracket \mathbf{D}_{obj} \rrbracket = \llbracket End(ray(\mathbf{d})) \rrbracket$

We assume that the interpretation function, $[\![.]\!]$, fully determines the value of the deixis in the context, supplied by the common ground, which we discuss below. In (10b), the action gesture type, G_{Af} , consists of an action-object pairing, where the action, **a**, is applied to the object, b_1 , in some prototypical manner. The strategies available are outlined in (12-14).

(12) a. ACTION-OBJECT: e.g., grab [Object]

- b. $GvP_1 \rightarrow G_{Af} D_{obj}$ (Action Focus) $\rightarrow D_{obj} G_{Af}$ (Object Focus)
- (13) a. ACTION-RESULT: e.g., put [Object] at [Location]
 - b. $GvP_2 \rightarrow G_{Af} D_{obj} D_{loc}$ (Action Focus) $\rightarrow D_{obj} G_{Af} D_{loc}$ (Object Focus) $\rightarrow D_{obj} D_{loc} G_{Af}$ (Transition Focus)
- (14) a. ACTION-RESULT: e.g., move [Object] [Direction]
 - b. $GvP_3 \rightarrow G_{Af} D_{obj} D_{dir}$

(

As mentioned above, the deictic gesture in (9a) and (10a) actually serves to indicate both a location and objects within that location, suggesting that deixis denotes a *dot object*, viz., PHYSOBJ•LOCATION (Pustejovsky, 1995; Asher and Pustejovsky, 2006; Asher, 2011). Either of these type components may be exploited by the deictic reference, which is then interpreted in context, either as a selection (exploiting the PHYSOBJ) or as a destination (exploiting either). For example, should an object b_1 already be selected through a deixis \mathbf{d}_a , as in (10a), a subsequent deixis \mathbf{d}_b may be interpreted as selecting a destination location in isolation (in which case the interpretation exploits the LOCATION of \mathbf{d}_b), or as selecting a location relative to another object (exploiting the PHYSOBJ type of \mathbf{d}_b). We discuss this further below.

With conventional treatments of continuation-style passing within the utterance, all linguistic expressions are continuized within the sentence. This has a distinct advantage in multimodal processing, because it allows for an *informational distribution* among the expressions being used in composition to form larger meanings.

By treating the common ground as a state monad, as described above, we can continuize the composition above the level of the sentence as well. Following (Van Eijck, 2001), the approaches taken by (De Groote, 2001) and (Asher and Pogodalla, 2010), and then further developed in (Van Eijck and Unger, 2010), we represent a context as a stack of items and the type of left contexts to be lists of entities, [e]. Right contexts will be interpreted as continuations: a discourse that requires a left context to yield a truth value. The type of a right context is therefore $[e] \rightarrow t$. Hence, context transitions get the type $[e] \rightarrow [e] \rightarrow t$; they are characteristic functions of binary relations on contexts. The continuized semantics for gesture phrases is in (15).

15) a.
$$\mathbf{S}_{G} \to (\mathbf{NP}) \mathbf{GvP}$$

 $[S]] = ([[\mathbf{NP}]] [[\mathbf{GvP}]])$
b. $\mathbf{GvP}_{1} \to \mathbf{G}_{af} \mathbf{D}_{Obj}$
 $[[\mathbf{GvP}_{1}]] = \lambda j. ([[\mathbf{D}_{Obj}]]; \lambda j'. (([[\mathbf{G}_{af}]]j')j))$
c. $\mathbf{GvP}_{2} \to \mathbf{G}_{af} \mathbf{D}_{Obj} \mathbf{D}_{Loc}$
 $[[\mathbf{GvP}_{2}]] = \lambda k. ([[\mathbf{D}_{Loc}]]; \lambda j. ([[\mathbf{D}_{Obj}]]; \lambda j'. ((([[\mathbf{G}_{af}]]j')j)k))$
d. $\mathbf{GvP}_{3} \to \mathbf{G}_{af} \mathbf{D}_{Obj} \mathbf{D}_{Dir}$
 $[[\mathbf{GvP}_{3}]] = \lambda k. ([[\mathbf{D}_{Dir}]]; \lambda j. ([[\mathbf{D}_{Obj}]]; \lambda j'. ((([[\mathbf{G}_{af}]]j')j)k))$

The discourse updating operation is accomplished through continuation-passing as well, as in (Asher and Pogodalla, 2010). We apply a CPS transformation to arrive at

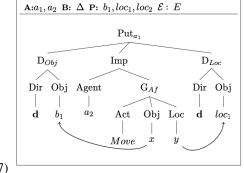

the continuized type for each expression, notated as an overlined expression (Van Eijck and Unger, 2010). Given the current discourse, T, and the new utterance, C, we take the integration of C into D as follows:

(16) $\llbracket \overline{(\mathbf{T.C})} \rrbracket^{M,cg} = \lambda k. \llbracket \overline{\mathbf{T}} \rrbracket (\lambda n. \llbracket \overline{\mathbf{C}} \rrbracket (\lambda m. k(m n)))$

To illustrate how continuations help in the interpretation of gesture sequences, consider a gestural expression denoting the imperative below.

SINGLE MODALITY (GESTURE) IMPERATIVE
HUMAN ₁ : $\mathcal{G} = [points to the purple block]_{t1}$
HUMAN ₂ : $\mathcal{G} = [makes move gesture]_{t2}$
HUMAN ₃ : $\mathcal{G} = [points to the red block]_{t3}$

Through its own continuation, the referent identified in the first deixis, \mathbf{D}_{Obj} , is passed to the action $(\lambda k.k(\llbracket \mathbf{Move} \rrbracket))$, while the continuized interpretation of the action delays the computation of its argument until the appropriate binding has been identified. Finally, the goal location for the movement selected for by the *move* gesture is identified through the action of the continuized location deixis, \mathbf{D}_{Loc} . This is illustrated in (18), along with the common ground structure that is computed, shown in (17).

(18) $\llbracket \mathbf{D}_{Obj}.\mathbf{Move}.\mathbf{D}_{Loc} \rrbracket = \lambda k.(\llbracket \mathbf{D}_{Loc} \rrbracket; \lambda j.(\llbracket \mathbf{D}_{Obj} \rrbracket; \lambda j'.((\llbracket \mathbf{Move} \rrbracket j')j)k))$

Given a description of the gesture grammar as used in our multimodal dialogues, let us explore a communicative act that exploits a combination of both speech and gesture, (S, G). We can identify three configurations for how a language-gesture *ensemble* can be interpreted, depending on which modality carries the majority of semantic content: (a) language with *co-speech gesture*, where language conveys the bulk of the propositional content and gesture adds situated grounding, affect, effect, and presuppositional force (Cassell *et al.*, 2000; Lascarides and Stone, 2006; Schlenker, 2018; Schlenker, 2020); (b) *co-gestural speech*, where gesture plays this role (Pustejovsky, 2018); and (c) a truly mixed modal expression, where both language and gesture contribute equally to the meaning. In practice, while many of the interaction in our dialogues have this property, the discourse narrative is broadly guided by gesture. For this reason, we will view the multimodal interactions as gesture with *co-gestural speech*.

A multimodal communicative act, C, consists of a sequence of gesture-language ensembles, (g_i, s_i) , where an ensemble is temporally aligned in the common ground. Let us assume that a linguistic subexpression, s, is either a word or full phrase in the utterance, while a gesture, g, comports with the gesture grammar described above.

(19) **Co-gestural Speech Ensemble**: $\begin{bmatrix} \mathcal{G} & g_1 & \dots & g_i & \dots & g_n \\ \mathcal{S} & s_1 & \dots & s_i & \dots & s_n \end{bmatrix}$

We assume an aligned language-gesture syntactic structure, for which we provide a continuized semantic interpretation. Both of these are contained in the common ground state monad introduced above in (6). For each temporally indexed and aligned gesture-speech pair, (g, s), we have a continuized interpretation, as shown below. Each modal expression carries a continuation, k_g or k_s , and we denote the alignment of these two continuations as $k_s \otimes k_g$, seen in (20).

(20)
$$\lambda k_s.k_s([\mathbf{s}])$$

 $\lambda k_g.k_g([\mathbf{g}])$
 $\lambda k_s \otimes k_g.k_s \otimes k_g([(\mathbf{s},\mathbf{g})])$

We bind co-gestural speech to specific gestures in the communicative act, within a common ground, CGS. A dashed line in (21) indicates that a co-gestural speech element, S, is aligned with a particular gesture, G. For example, consider the co-gestural speech expression shown below.

SINGLE MODAI	LITY (GESTURE) IMPERATIVE
	$S = \text{That}_{t1}$ $G = [points to purple block]_{t1}$ $G = [makes grab gesture]$

The CG structure for this expression, $\begin{bmatrix} \mathcal{G} & D_{Obj} & \overline{Grab_g} \\ \mathcal{S} & THAT & _ \end{bmatrix}$, is shown in (21).

 $(21) \ [\![\langle \mathsf{THAT}, \mathbf{D}_{Obj} \rangle . \langle _, \mathbf{Grab} \rangle]\!] = \lambda k_s \otimes k_g . ([\![\mathbf{D}_{Obj}]\!]; \lambda j_g . (([\![\mathbf{Grab}]\!] j_g) k_s \otimes k_g))$

Common ground updates will also include executing modal operations over the belief space **B**, where each new element from the discourse is introduced via a *public announcement logic* (PAL) formula, and each new perceived object or relation is introduced into **P** via an analogous *public perception logic* (PPL) formula (Plaza, 2007; Van Ditmarsch *et al.*, 2007; Van Benthem, 2011). We will use $[\alpha]\varphi$ to denote that an agent " α *knows* φ ". Public announcements are implemented as: $[!\phi_1]\phi_2$. Any proposition, φ , in the common knowledge held by two agents, α and β , is computed as: $[(\alpha \cup \beta)^*]\varphi$.

Similarly, an agent α 's perception is encoded as sets of accessibility relations, α , between situations. What is seen in a situation is encoded as either a proposition, φ , or existential statement of an object, x, \hat{x} . $[\alpha]_{\sigma}\varphi$ denotes that agent " α perceives that φ ". $[\alpha]_{\sigma}\hat{x}$ denotes that agent " α perceives that there is an x."

Given the theory of two-level affordances outlined here (Gibsonian and Telic), we can naturally think of objects as antecedents to the actions performable on them. For example, for each object in (22), we can identify the attached behaviors.

(22) a. block: Pick me up!, Move me!b. cup: Pick me up!, Drink what's in me!c. knife: Pick me up!, Cut that with me!

This naturally suggests that affordances are a subclass of continuations. For example, both *cup* and *block* have similar Gibsonian affordance values, but quite distinct Telic affordance values. This could be distinguished by the nature of their respective Telic continuation sets as follows, where **sel** is a function that selects a suitable discourse antecedent inside the continuation set (Asher and Pogodalla, 2010): $\lambda k_{Gib} \otimes k_{Telic}.k_{Gib} \otimes k_{Telic}(cup)$, $grab \subseteq$ **sel** k_{Gib} , $drink \subseteq$ **sel** k_{Telic} , $\lambda k_{Gib} \otimes k_{Telic}.k_{Gib} \otimes k_{Telic}(block)$, $grab \subseteq$ **sel** k_{Gib} , $pick_up \subseteq$ **sel** k_{Gib} , $move \subseteq$ **sel** k_{Gib} . This is the subject of ongoing research within our studies.

6. Experiments with Multimodal Dialogues

6.1. Aspects of Multimodal Compositionality

In this section, we provide additional formal analysis to experimental data gatheref from multimodal dialogues between a human and a computational agent, represented as an avatar in VoxWorld, and human-robot interactions. We examine extracts from dialogues between humans and computational agents in various tasks, in order to examine the nature of the communicative act in the context of the common ground structure. We illustrate how the situated meaning of the multimodal expression is constructed in each case. In particular, we look at three aspects of multimodal compositionality in these examples:

- (23) a. Generating Referring Expressions using different modalities;
 - b. Generating and interpreting action and event expressions;
 - c. Generating full action descriptions using both gesture and language.

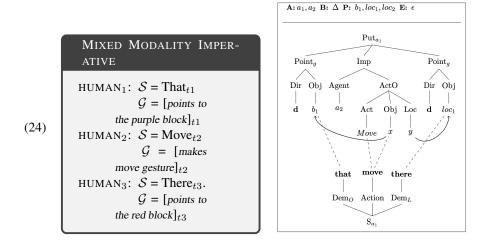

Recall that a multimodal communicative act, C, consists of a sequence of gesturelanguage ensembles, (g_i, s_i) , where an ensemble is temporally aligned in the common ground. For the examples below, we annotate the dialogue with the contribution of both speech and gesture for each agent. Each dialogue turn encodes a multimodal ensemble, $\begin{bmatrix} S \\ G \end{bmatrix}$, which may or may not be realized in both modalities. In the annotation below, alignment between the modalities is indicated through a temporal indexing on the appropriate modal expression, e.g., t_i .

Since we use both speech and gesture to indicate objects and location (deixis), and actions (iconic gesture), we bias our speech recognition toward syntactic categories that represent partial information (e.g., noun phrases for objects, prepositional phrases for locations, verb phrases for actions), using incremental predictivity (cf. (Hough

et al., 2015)) and we parse the input in both directions, which allows us to take inputs like "put a block on the purple block" and make sure that "a block" does not resolve to the purple block so as to prevent the agent from putting the purple block on itself.

Figure 8. Situated dialogue: gesture and co-gestural speech imperative.

 $\lambda r_s \otimes r_g . (\llbracket \langle \text{THERE}, \mathbf{D}_{Loc} \rangle \rrbracket \lambda k_s \otimes k_g . (\llbracket \langle \text{THAT}, \mathbf{D}_{Obj} \rangle \rrbracket; \lambda j_s \otimes j_g . ((\llbracket \langle \text{MOVE}, \mathbf{Move} \rangle \rrbracket j_s \otimes j_g) k_s \otimes k_g)) r_s \otimes r_g)$

6.2. Multimodal Referring Expressions

(Krishnaswamy and Pustejovsky, 2019) present data in the form of simulated situations showing an agent (Diana) indicating various object in a scene with an accompanying definite referring expression for each. These referring expressions may take the form of deictic gesture only, a spoken description only with no demonstratives (e.g., "the red block in front of the knife and left of the green block"), and a mixed-modality referring expression as in Figure 9 (right). Figure 9 (left) shows a sample still that accompanies the utterance in the right half.

The Embodied Multimodal Referring Expressions dataset consists of 1,500 of these referring expressions for various objects across various configurations were

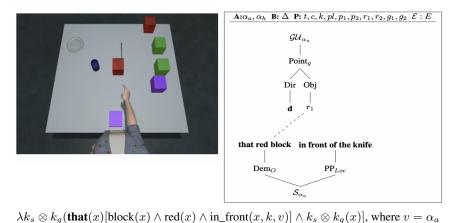

Figure 9. Left: Sample still from the EMRE datase. Right: Common-ground structure for "that red block in front of the knife". The semantics of the referring

expression is shown below, where it encodes a continuation for each modality, k_s and k_g , which will apply over the object in subsequent moves in the dialogue.

shown to a set of annotators on Amazon Mechanical Turk, where they were evaluated on a Likert-type scale for naturalness of the depicted referring expression for the indicated object. The authors showed a clear preference for the multimodal referring expressions, suggesting that the redundancy provided by co-occurring language and gesture made for the clearest, most natural references to objects.

We extracted formal features from the data in the form of common ground structures and used these to train a neural net to predict the naturalness of a given referring expression. For instance, an agent might introduce a new object into the scene, making common the knowledge of its existence. Or one agent a may use a term t in a definite description which makes public the knowledge of a's interpretation of t.

	Raw features		Raw feat. + SE	
μ Acc. (1K)	0.6757		0.6429	
σ Acc. (1K)	0.0230		0.0111	
	Raw +	Raw	+	Formal
	form.	form	. + SE	only
μ Acc. (1K)	0.7214	0.667	71	0.7471
σ Acc. (1K)	0.0398	0.024	43	0.0269

These formal features proved to strengthen the ability of a neural network to predict the natural quality of a referring expression beyond the very strong predictors of naturalness, such as modality.

Figure 10. Classification accuracy after 1000 epochs using formal features (mean and standard deviation over 7-fold cross-validated sample)

Fig. 10 shows that inclusion of formal features derived from the elements of common-ground structures improved classifier prediction accuracy by between 7% and 11% relative to a baseline prediction using the raw features of the EMRE dataset (these contain situational information about the specific configuration

in which the referring expres-

sion was generated), as well as sentence embedding representations of the referring expression itself. This suggests that common ground structures provide a dense but interpretable representation of the discourse state which facilitates the generation of natural, situation appropriate referring expressions.

6.3. Interruptions and Corrections in Dialogue

By establishing entities in a common ground structure such that they can be recombined as appropriate and interpreted in context allows us to built asynchronous agent behaviors capable of being interrupted and corrected.

	FERENCE CORREC-
TIO	N/REPAIR
н:	$\mathcal{G} = [points \ to \ area$
	around yellow and
	white blocks]
D:	$S = Okay{t1}$
	$\mathcal{G} = [picks up yellow]$
	$block]_{t1}$
н:	S = No, the white
	one.
D:	$S = Okay{t2}$
	$\mathcal{G} = [picks up white]$
	$block]_{t2}$

Figure 12. *Correcting and undoing an action.*

The user ambiguously indicates both the yellow and white blocks through deixis. When Diana chooses the yellow block (giving rise to $\lambda k.k(grab)$ $\implies M, cg_1 \models grab(yellow)$), the user corrects this with "no, the white one," and the yellow block is unbound from its status as focus, which is reassigned to the white block.

Correction (shown in Figure 11) is currently implemented by performing three functions: (a) **undo**, which recontinuizes an expression which has saturated its parameters, i.e., **undo** $k = \lambda k.k(grab)$; (b) **Rewind**, which reintroduces the previous monad; and (c) **Reassign**, which takes the corrected value and assigns it, resulting in $M, cq_2 \models grab(white)$.

In this manner, parameters can be unbound from either object or location argument, depend-

ing on the typing of the content communicated. Figure 12 shows one such situation, where the replacement content "on the white one" is evaluated to a location. The state monad containing the location on the blue block is rewound, and the argument reassigned to the location on top of the white block. Had the utterance been "the white one," the action would be reassigned with the white block as the theme, with the previously-existing target location, and Diana would put down the yellow block and put the *white* block on the blue block.

CORRECTING AND UNDOING PARAMETER BINDING IN ACTIONS

HUMAN: $S = \text{Take this}_{t1}$ one. $\mathcal{G} = [points to the purple block]_{t1}$ HUMAN: S = Wait, the yellow one. DIANA: $S = \text{Okay}_{t2}$. $\mathcal{G} = [grabs the yellow block]$ HUMAN: $\mathcal{G} = [points to top of blue block]$ DIANA: $S = \text{Okay}_{t3}$. $\mathcal{G} = [moves yellow block to top of blue block]_{t3}$ HUMAN: S = Wait, on the white one. DIANA: $\mathcal{G} = [moves yellow block to top of white block]$

6.4. Affordance Structure and Transfer Learning

In her interactions, Diana may come across objects with different structures and affordances from the typical Blocks World scenario. In these cases, the semantics of each object provided by VoxML allows Diana to learn new gestures associated with specific affordances of specific objects. The "Affordance Learning in KitchenWorld" dialogue specifies an interaction in which this takes place (shown in Figure 13).

AFFORDANCE LEARNING IN KITCHENWORLD	
HUMAN: $S =$ The plate.	
DIANA: $S = Okay_{t1}$	
$\mathcal{G} = [points to the plate]_{t1}$	
HUMAN: $\mathcal{G} = [$ makes "claw down" gesture $]$	
DIANA: $S =$ Should I grasp it like this _{t2} ?	
$\mathcal{G} = [grasps plate from the side]_{t3}$	
HUMAN: $S = $ Yes.	
DIANA: $S =$ Is there a gesture for that?	
HUMAN: $G = [makes "grasp plate" gesture]$	

Using a random forest classifier, the gesture the humans makes to associate with the specific affordance is situated in the search space defining the existing known gestures. Those learned grasp semantics can then be propagated down to any other event containing [[GRASP]] as a subevent, as shown below.

(25) $grasp(e_1, AG, y)$; while $(hold(AG, y) \land on(y, SURF) \land \neg at(y, LOC))$, $move_to(e_2, AG, y, LOC))$; if $(at(y, LOC), ungrasp(e_3, AG, y))$

That is, **while**(C, A) states that an activity, A, is performed only if a constraint, C, is satisfied at the same moment. Therefore, if the agent encounters a [[SLIDE]] action with an outstanding variable $(\lambda y.slide(y, loc))$, and the human supplies a gesture denoting grasp(plate), then the agent can directly lift grasp(plate) to the slide agent.

rectly lift grasp(plate) to the slide action and apply the argument plate to y: $\lambda y.slide(y, loc)@plate \Rightarrow \lambda y.slide(y, loc)$.

Affordance properties can also be transferred between objects. Given that similar habitats serve as necessary (but not, in isolation, sufficient) preconditions to certain behaviors (e.g., in

Figure 14. Synchronous Deixis and Language

order to be rolled, an apple, a cup, and a bottle must all be turned on their sides), the ability to assess an unknown object relative to known ones allows an agent to computationally transfer properties between them, to give the agent a handle on interacting with and discussing a novel object. Consider Figure 14, knowing that Diana here has no semantics for the object we would recognize as a bottle.

TRANSFERRING OBJECT AFFORDANCESHUMAN: S = What is that? $_{t1}$ \mathcal{G} = [points to the cup] $_{t1}$ DIANA: S = That's a cup $_{t2}$ \mathcal{G} = [points to the cup] $_{t2}$ HUMAN: S = And what is that? $_{t3}$ \mathcal{G} = [points to the bottle] $_{t3}$ DIANA: S = I don't know, but I could I grasp it like a cup $_{t4}$. \mathcal{G} = [points to the bottle] $_{t4}$ HUMAN: S = OK, go on.DIANA: \mathcal{G} = [grasps bottle from the side] $_{t5}$

In this dialogue, Diana is able to observe certain similarities in the shape and habitats of the cup and the bottle (e.g., current upright orientation, similar symmetry and size constraints), and infer that they might share some behaviors, which leads her to infer that a way to grasp the bottle would be like she grasps the cup. The close association between habitats and affordances and the structured encoding provided by VoxML allows us to perform this kind of transfer learning using methods similar to Skip-Gram word embedding models in natural language processing, by inferring a likely missing behavior given the current combination of circumstances. This behavior is then executed in the relevant manner in the right-side image of Figure 14.

7. Conclusion

Multimodal peer-to-peer interfaces require robust integration of conversational modalities in a naturalistic fashion. Here we outline the first steps toward such integration, based on the logic of a multimodal simulation semantics and 3D environment as the platform for shared common ground. We provide our computational agent with a framework for some of the faculties natively available to humans using sophisticated computer vision techniques to recognize gesture and by laying the groundwork for a modal logic of synthetic vision. The result is a framework and platform that interweaves linguistic and non-linguistic modalities to facilitate the completion of a shared task by exploiting the relative strengths of linguistic and non-linguistic context to exchange information in a situated communication.
